

Causal Transformer on 10 TCGA cancer types ($d = 200$)

(a) Per-cancer CT edge count at $d = 200$

(b) Cluster coherence per cancer (co-expression proxy)

Top: post-hoc CT edge counts (coherence-screened). Bottom: coherence = fraction of CT-selected edges whose two genes are co-expressed (Pearson $r > 0.4$) within a K-means cluster --- a biological-plausibility screen, NOT causal precision. CT and NOTEARS use different post-hoc rules, so counts are not directly comparable.
